ENGINEERING.

TOPIC : HOSPITAL MANAGEMENT SYSTEM

DETAILS:

This system is designed to simulate a real hospital reception process in a simple and organized way. It manages complete patient registration by collecting important details such as Name, Father Name, Cnic, Age, Weight and their disease.

After collecting the patient's information, the system reviews the symptoms and suggests the most suitable doctor. It also provides useful details like the doctor's room number, availability time, and current rush status so that the patient can decide when to visit.

The system guides patients about the best visiting time according to doctor availability and workload. In urgent cases, it highlights the appropriate doctor for immediate consultation.

After processing, a receipt is generated for the patient which includes doctor details, appointment information, and a unique identification code. This code is used later for verification when the patient returns to the reception after visiting the doctor.

Using this code, the system helps in verifying patient records, managing fee collection, and keeping track of patient visits in an organized manner. Overall, this project represents a simple but effective simulation of hospital reception operations and improves organization, patient handling, and communication flow.
